## Mørke flekker i laksefilet

-Årsaker til forekomst og forebyggende tiltak

2012-2015

### Prosjektbeskrivelse

#### Sammendrag:

Det overordnede målet er å forhindre dannelse av mørke flekker i laksefilet. I dette ligger en soken etter årsaker til at flekkene oppstår for at kunne anbefale tiltak som kan bidra til å løse problemet. Aktivitetene i prosjektet er delt i fire arbeidspakker (AP): <sup>1</sup>Kartlegging, <sup>2</sup>Vaksine og helse, <sup>3</sup>Fôr og <sup>4</sup>Sortering og skade. Det vil være et nært samarbeid mellom AP1-4, som vil gå parallelt i perioden 2012 og ut 2014.

#### Går til:

Fiskeri og havbruksnæringens  
forskningsfond

Rutinemessig kartlegging av forekomst av mørke filetflekker utføres av kvalitetskontroller ved filetanlegg med geografisk spredning. Registreringene danner grunnlag for etterrettelig statistikk samt dybdeanalyse for å avdekke årsakssammenhenger. To basispopulasjoner med PIT-tag merket uvaksinert og vaksinert (ulike regimer) laks produseres: nullårssmolt (BP0+) og ettårssmolt (BP1+). Etter vaksinering undersøkes laksen jevnlig for mørke filetpigmenter frem til slakt. Produktjonsparametere, morfometri og blod analyses også. Mørke filetflekker undersøkes ved avbildende spektroskopi, foto, histologi, sammensetning og genuttrykk. Øvrige kvalitetsegenskaper undersøkes av utvalgt fisk. BP0+ vil i en 3 måneders periode for slakt få et sluttfør med og uten forhøyet sink, vitamin E eller förtoksiner (ulike vaksineregimer blandet i merder). BP1+ vil undersøkes mht effekt av lavt sinknivå frem til vaksinering samt fra sjoutsett til slakt. I

SalmoBreed

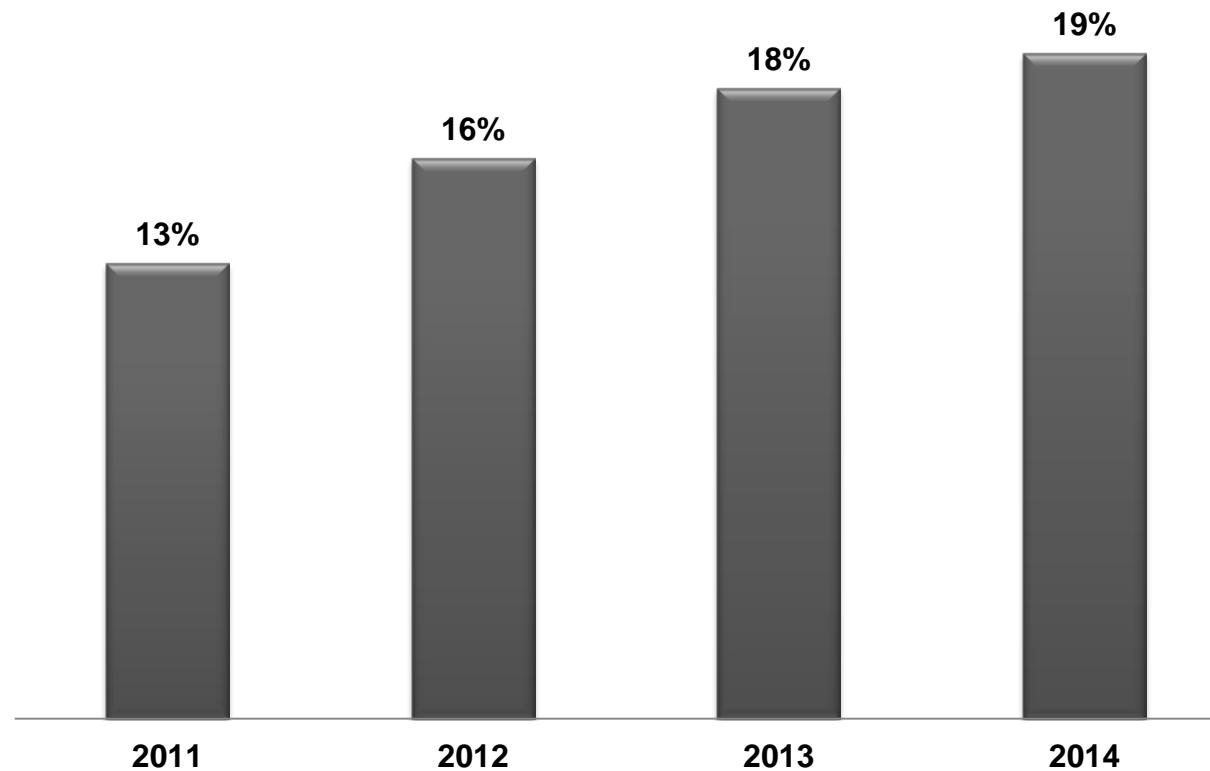

# The project

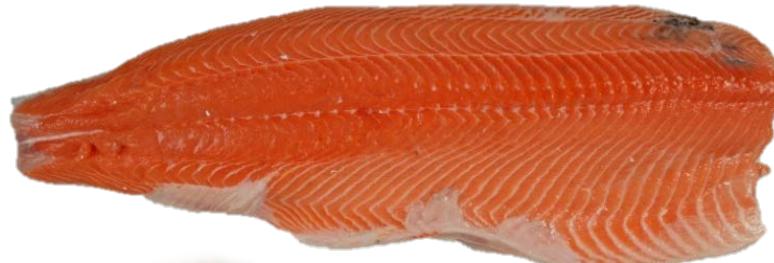

# Norwegian salmon with dark spots

**93% of the spots located in the rib area, 2-4 cm below the backbone**

# Dark pigmentation

**Blood**

**Scar**

**Melanin**

# Challenges

**Many factors vary simultaneously in commercial farming**

- Fish material, feed, environment, health
- Useful to combine monitoring of practical farming with small scale experiments, under controlled conditions

# Fish experiment

## Melanin in abdominal wall

- Observed before vaccination

## Melanin in organs

- Observed after vaccination

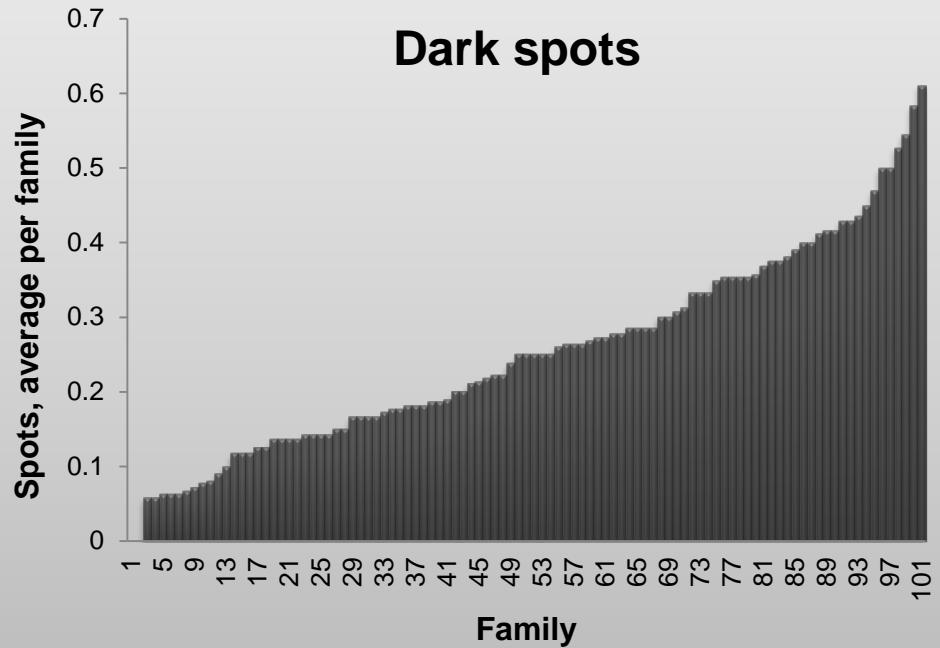

## Melanin in fillets

- Observed in seawater in vaccinated and unvaccinated fish
- $\frac{1}{2} \text{ kg } 5\%$ ,  $1 \text{ kg } 10\%$ ,  $3 \text{ kg } 10-16\%$

# Breeding & genetics

## Preliminary results

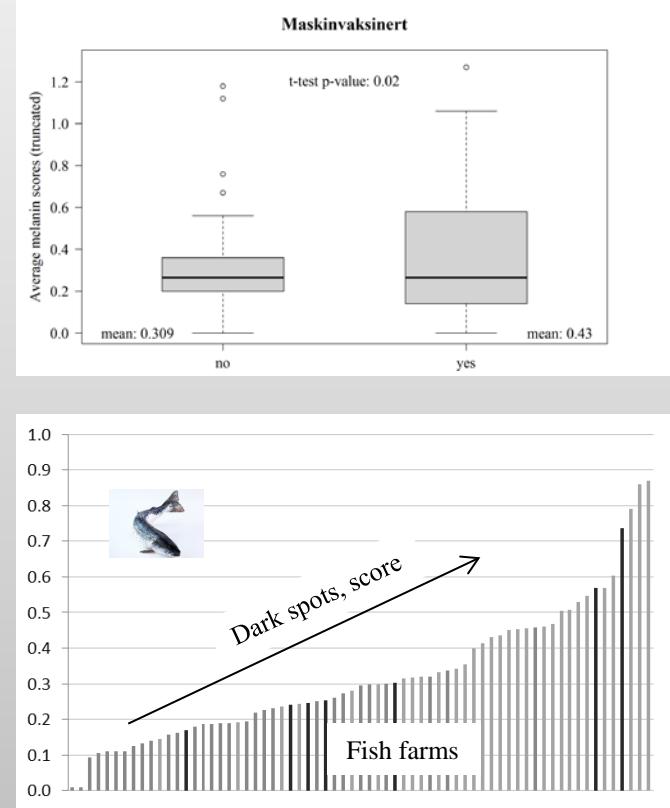

Selective breeding can not solve the problem with dark stained salmon fillets

# The response to inflammation is affected by

- Type of vaccine
- Vaccination
- Feed
- Rearing conditions

Primary cause ?

All background information is anonymized

# norsk fiskeoppdrett

# FAQ, frequently asked questions (www.fhf.no)

Updated December 2013

## MELANIN DEPOSITION IN SALMON FILLETS

### Frequently asked questions

Dark discolouration of salmon fillets is mainly due to the deposition of melanin pigments. The discolouration may have different manifestations, from localized spots to more diffuse and widespread **melanisation** on the fillet side or under the skin/subcutaneously. Dark stained fillets cannot be sold as high quality products and therefore represent a significant economic problem for the salmon farming and processing industry

### What is melanin?

- Melanin is a group of natural pigments found in most plants and animals
- Melanin is a powerful natural antioxidant
- In humans, melanin (**melanopsin**) is the primary determinant of skin **colour**.

### What causes melanin deposition in salmon fillets?

- Melanin pigments are deposited as a response to tissue damage or local inflammatory conditions
- Melanin deposition is a natural part of a fish's immune system
- Dark discolouration of salmon fillets is mainly due to melanin deposition, but dark spots can also contain blood pigments and scar tissue or a combination of melanin, blood and scar tissue.
- The causality is complex, and not related to one single cause.

### Is it safe to consume fillets with melanin deposits

- Melanin is a safe and natural antioxidant
- Melanin can be used as a natural antioxidant in the food, cosmetic and pharmaceutical industries
- Dark pigments in various foods, such as caviar, are **melanins**.

Updated December 2013

### Occurrence of melanin spots in salmon fillets

- Approximately 12% of Norwegian salmon fillets have lightly stained spots smaller than 3cm in diameter, and 2% of the fillets have darker spots larger than 3cm on average.
- Most spots (70%) are located in the front part of the abdomen
- Dark spots are also observed in wild living salmon, hence it is not likely that the phenomenon will disappear completely

### What is being done to reduce the presence of dark fillet spots

- The Norwegian Seafood Research Fund (FHF), on behalf of the farming industry, has supported research on dark fillet spots since 2008 to reveal causes, provide reliable statistics and to define measures to reduce the problem. The research within this area was intensified in 2012, involving several industrial stakeholders and research communities.
- Reliable statistics require good, consistent, continuous and comprehensive recording of dark fillet spots. Therefore, unified registrations at filleting plants along the Norwegian coast have been developed and implemented. Registrations of frequency and severity together with background data (genetics, vaccines/fish health, feed, rearing, harvesting etc.) is collected in a database to provide reliable and updated statistics. Information on fish origin is used to search for causes to the problem. However, such an epidemiological approach requires patience as the results evolve on a long-term basis. Updated statistics on the frequency of dark spots are published continuously.
- Specific ongoing research projects (apart from the registrations/ epidemiological study)
  - Vaccines and vaccination
  - Food composition
  - Environmental rearing conditions
  - The importance of physical trauma and stress
  - In-depth characterization of fillets with dark pigmentation to improve our ability to define causes
